Fast-slow systems

Let $\dot{Y} = g(Y)$ be some chaotic ODE with state space Λ and ergodic invariant measure μ . We consider **fast-slow** systems of the form

$$\begin{aligned}\frac{dX^{(\varepsilon)}}{dt} &= \varepsilon^{-1}h(X^{(\varepsilon)}, Y^{(\varepsilon)}) + f(X^{(\varepsilon)}, Y^{(\varepsilon)}) \\ \frac{dY^{(\varepsilon)}}{dt} &= \varepsilon^{-2}g(Y^{(\varepsilon)}),\end{aligned}$$

where $\varepsilon \ll 1$ and $h, f : \mathbb{R}^e \times \Lambda \rightarrow \mathbb{R}^e$ and $\int h(\cdot, y) \mu(dy) = 0$. Also assume that $Y(0) \sim \mu$.

The aim is to characterize the **distribution** of $X^{(\varepsilon)}$ as $\varepsilon \rightarrow 0$.

Fast-slow systems as SDEs

Consider the simplified **slow** equation

$$\frac{dX^{(\varepsilon)}}{dt} = \varepsilon^{-1} h(X^{(\varepsilon)}) v(Y^{(\varepsilon)}) + f(X^{(\varepsilon)})$$

where $h : \mathbb{R}^e \rightarrow \mathbb{R}^{e \times d}$ and $v : \Lambda \rightarrow \mathbb{R}^d$ with $\int v(y) \mu(dy) = 0$.

If we write $W^{(\varepsilon)}(t) = \varepsilon^{-1} \int_0^t v(Y^{(\varepsilon)}(s)) ds$ then

$$X^{(\varepsilon)}(t) = X^{(\varepsilon)}(0) + \int_0^t h(X^{(\varepsilon)}(s)) dW^{(\varepsilon)}(s) + \int_0^t f(X^{(\varepsilon)}(s)) ds$$

where the integral is of Riemann-Lebesgue type.

Invariance principle for $W^{(\varepsilon)}$

We can write $W^{(\varepsilon)}$ as

$$W^{(\varepsilon)}(t) = \varepsilon \int_0^{t/\varepsilon^2} v(Y(s)) ds = \varepsilon \sum_{j=0}^{\lfloor t/\varepsilon^2 \rfloor - 1} \int_j^{j+1} v(Y(s)) ds$$

The assumptions on Y lead to **decay of correlations** for the sequence $\int_j^{j+1} v(Y(s)) ds$.

One can show that $W^{(\varepsilon)} \Rightarrow W$ in the sup-norm topology, where W is a multiple of Brownian motion.

What about the SDE?

Since

$$X^{(\varepsilon)}(t) = X^{(\varepsilon)}(0) + \int_0^t h(X^{(\varepsilon)}(s)) dW^{(\varepsilon)}(s) + \int_0^t f(X^{(\varepsilon)}(s)) ds$$

This suggest a limiting SDE

$$X(t) = X(0) + \int_0^t h(X(s)) \star dW(s) + \int_0^t f(X(s)) ds$$

But how should we interpret $\star dW$?

Continuity of the solution map

The solution map takes “noisy path space” to “solution space”

$$\Phi : W^{(\varepsilon)} \mapsto X^{(\varepsilon)}$$

If this map were **continuous** then we could lift $W^{(\varepsilon)} \Rightarrow W$ to $X^{(\varepsilon)} \Rightarrow X$.

We want to define a map $\Phi : U \rightarrow X$ where U is a noisy path and

$$X(t) = X(0) + \int_0^t h(X(s))dU(s) + \int_0^t f(X(s))ds$$

This is problematic for two reasons.

1 - The solution map Φ is only defined for *differentiable* noise. But $W^{(\varepsilon)} \Rightarrow W$ and Brownian motion is *not differentiable*.

2 - Any attempt to define an extension of Φ to Brownian-like objects will fail to be continuous. ie. We can find a sequence $W_n \Rightarrow W$ but $\Phi(W_n) \not\Rightarrow \Phi(W)$.

The lesson is, we must use extra information about the noise to construct a continuous extension.

Rough path theory (Lyons '97)

Suppose we are given a path $\mathbf{U} : [0, T] \rightarrow \mathbb{R}^{d \times d}$ which is (formally) an iterated integral

$$\mathbf{U}^{ij}(t) \stackrel{\text{def}}{=} \int_0^t U^i(s) dU^j(s).$$

Given $\mathbf{U} = (U, \mathbf{U})$ we can construct a solution

$$X(t) = X(0) + \int_0^t h(X(s)) d\mathbf{U}(s) + \int_0^t h(X(s)) ds$$

The map

$$\Phi : (U, \mathbf{U}) \mapsto X$$

is an extension of the classical solution map and is **continuous** with respect to the “rough path topology”.

Convergence of fast-slow systems

If we let

$$\mathbb{W}^{ij,(\varepsilon)}(t) = \int_0^t W^{i,(\varepsilon)}(r) dW^{j,(\varepsilon)}(r)$$

then $X^{(\varepsilon)} = \Phi(W^{(\varepsilon)}, \mathbb{W}^{(\varepsilon)})$.

Due to the continuity of Φ , if $(W^{(\varepsilon)}, \mathbb{W}^{(\varepsilon)}) \Rightarrow (W, \mathbb{W})$, then $X^{(\varepsilon)} \Rightarrow X$, where

$$X(t) = X(0) + \int_0^t h(X(s)) dW(s) + \int_0^t h(X(s)) ds$$

with $W = (W, \mathbb{W})$.

We have the following result

Theorem (K, Melbourne '14)

If the *fast* dynamics are “*sufficiently chaotic*”, then $(W^{(\varepsilon)}, \mathbb{W}^{(\varepsilon)}) \Rightarrow (W, \mathbb{W})$ where W is a Brownian motion and

$$\mathbb{W}^{ij}(t) = \int_0^t W^i(s) dW^j(s) + \lambda^{ij} t$$

where the integral is Ito type and

$$\lambda^{ij} = \int_0^\infty \mathbf{E}_\mu(v^i v^j(Y(s))) ds .$$

$$\text{Cov}^{ij}(W) = \int_0^\infty \mathbf{E}_\mu(v^i v^j(Y(s)) + v^j v^i(Y(s))) ds .$$

Homogenized equations

Corollary

Under the same assumptions as above, the *slow* dynamics $X^{(\varepsilon)} \Rightarrow X$ where

$$dX = h(X)dW + \left(f(X) + \sum_{i,j,k} \lambda^{ij} \partial^k h^i(X) h^{kj}(X) \right) dt .$$
